## **Lasik Eye Surgery**

LASIK is performed in two steps. The first step is to create a flap oftissue. Atissue. Atissue.
suction ring is applied to the eye, holding the eye in place. The step in the procedure can sometimes cause small
blood vessels toverb resulting in bleeding orhemorrhage into the white of the eye,
harmless side effect that resolves withinweeks. Increased suction typically causes a transient
Verb ending in ing of Noun in the treated eye. Once the eye is immobilized, the flap is created. This
process is achieved with a mechanical Noun using a metal blade, or a Adjective laser
(procedure known as IntraLASIK) that creates a series of tiny closely arranged bubbles within the
cornea. A hinge is left at one end of this flap. The flap is folded back, revealing the the middle
section of the cornea. The process of lifting and folding back the flap can be uncomfortable.
The second step of the procedure is to use an excimer laser to remodel the Adjective Noun. The
laser vaporizesin a finely controlled manner without damaging adjacentb
releasing the molecular bonds that hold the cells together. No burning with heat or actual cutting is required to
ablate the tissue. The layers ofremoved are tens of micrometers thick. Performing the laser
ablation in the deeper corneal stroma typically provides for more rapid Adjective Plural noun and
less pain.
