Gabriella Garcia & Marissa de la Cruz

Climate change is a major threat to Remember that organisms are adapted to their eniviorments
and have specific tolerance reanges to temperature and other abiotic conditions. If conditions change beyond an
tolerance, the organism must move to a more suitable location or face extinction.
in fragmented habitats are particularly vulnerable to climate change because if conditions
change they may not be able to move easily to a suitable habitat. Estimates vary regarding the effects of climate
change on biodiversity. If global temperature increase 1.5C-2.5C over latetemperatures,
percent of species studied are likely to face increased risk of extinction. If the global temperature
increase goes beyond it is likely that 40-70 percent of species studied will face extinction.
